

Homework Assignment 2 (No Collaborators)

1. Exercise 6.5–8

Algorithm 1 Heap-Delete Algorithm

```

1: function HEAP-DELETE( $A, i$ )
2:    $A[i] \leftarrow A[n]$ 
3:    $n \leftarrow n - 1$ 
4:    $HEAPIFY(A, i)$ 
5: end function
  
```

2. **Exercise 7.2–3** The worst case running time of Quicksort is $\Theta(n^2)$ for a descending order array when the selection of the pivot is always the right element. In this case, each iteration of Partition reduces the size of the sub-array by 1. Thus, we have a recurrence relation equal to

$$T(n-1) + \Theta(n) = \Theta(n^2)$$

3. **Modified Exercise 8.2–1** First I transposed the alphabetical characters to numbers giving me the following values:

$$14 - 20 - 21 - 5 - 5 - 3 - 19 - 1 - 12 - 7 - 15 - 18 - 9 - 20 - 8 - 13$$

Then I used the counting sort algorithm to sort the array with indices from 0-25 representing each alphabetical value. The result is:

$$1 - 0 - 1 - 0 - 2 - 0 - 1 - 1 - 1 - 0 - 0 - 1 - 1 - 1 - 1 - 0 - 0 - 1 - 1 - 2 - 1 - 0 - 0 - 0 - 0 - 0$$

Forming the next index array, I obtained the following result by adding the previous index to the current index:

$$1 - 1 - 2 - 2 - 4 - 4 - 5 - 6 - 7 - 7 - 7 - 8 - 9 - 10 - 11 - 11 - 11 - 12 - 13 - 15 - 16 - 16 - 16 - 16 - 16$$

Finally, I used the index array to sort the original array into the following result:

$$A - C - E_1 - E_2 - G - H - I - L - M - N - O - P - R - S - T_1 - T_2 - U$$

4. **Exercise 8.2–4** Given n integers in the range of 0 to k as array A , create an k sized auxiliary array B initialized to 0. For each element i in A increment $B[A[i]]$. Compute the running sum for each element i in B and obtain the number of elements less than or equal to i . At this point, this is the initial steps in counting sort. To compute the number of elements in range $[a..b]$ we now have an $\Theta(1)$ computation: $B[b] - B[a]$ in range $[a..b]$
5. **Exercise 9.3–7** With the assumption that the set S is a sorted array of elements, we have the median given by index $n/2$. Then the closest k elements must be within the range of $(n-k)/2 \leq n/2 \leq (n+k)/2$. We can use linear search to traverse through these indices to find elements greater than $(n-k)/2$, not equal to $n/2$, and less than $(n+k)/2$.

6. Search Trees

Figure 1: Binary Search Tree

Figure 2: Red Black Tree

7. Dynamic Programming Implementations

- Find an optimal parenthesization to a matrix-chain product whose sequence of dimensions is $\langle 3, 5, 7, 9, 11 \rangle$.
- Determine an LCS of $\langle C, A, B, A, C, B, D \rangle$ and $\langle A, D, B, A, C, D \rangle$.
- Determine the cost and structure of an optimal binary search tree for a set of $n = 6$ keys with the following probabilities: $p_i = 0.05, 0.09, 0.10, 0.05, 0.12, 0.15, i = 1, \dots, 6$, respectively, and $q_i = 0.03, 0.06, 0.07, 0.11, 0.08, 0.05, 0.04, i = 0, \dots, 6$, respectively

8. Logger's Question

- Suppose you have a log of length $L = 4$ and $n = 3$ marked locations at some arbitrary locations d_1, d_2 and d_3 representing the endpoint of the log. Without loss of generality, cutting the log at d_1 first will result in a cost of $k = d_3 + d_2 - d_1$. Cutting the log at d_2 first will result in a cost of $k = d_3 + d_2$.
- We obtain the following recurrence: $c(i, j) = c(i, m) + c(m, j) + (d_j - d_i)$
-
